Toward a circuit modelling of cortico-thalamic

interactions in early human postnatal development. A population model describing the cortico-thalamic pathway of early postnatal development was constructed based on results obtained from anatomical and physiological studies. The model consists of eight non-linear units (NLUs) with excitatory synapses receiving input from two cortical areas. The number and distribution of connections has been implemented based on the histological and electrophysiological data. In spite of the simplicity of the model, the results were in good agreement with

Coal ash, the residue left when coal is burned to

produce electricity, is injected into wells under former coal-fired power plants that have been shut down. Credit: Adrian Wyld/Reuters (PhysOrg.com) -- Research team led by scientists from the University of California, Berkeley have shown that the sediment beneath wells where coal ash is injected contains arsenic and other toxic metals that have been shown to cause birth defects and other disease. At the center of the controversy over coal ash is the use of wells to inject the waste into the ground. Over the years, at least 25 percent of the wells have failed because of metal contamination, and the waste that would have once been dissipated into the ground has instead contaminated adjacent waters. But questions have been raised about the thoroughness with which the mining

industry has examined potential problems associated with the use of wells. The researchers from UC Berkeley, the University of Missouri, and the U.S. Geological Survey (USGS) looked at 11 coal-fired power plants that have been shut down in the U.S. and found that 14 percent of the wells have arsenic, and 7 percent have cadmium, lead and arsenic. While the standard for arsenic in groundwater is 0.020 milligrams per liter (mg/L), only 10 of the sampled wells registered that level. That amount is four times the level considered safe for drinking water by the U.S. Environmental Protection Agency. Other metals detected in the wells include copper, zinc and mercury. The arsenic has been associated with birth defects and asthma, and the cadmium, lead and arsenic have been shown

to increase levels of prostate cancer in men. "While the coal ash was injected into the wells before we were born, we are living with the damages that come with this waste. The findings speak to the risk of arsenic ingestion even without drinking water," said Leslie Roberts, co-author of the study and a UC Berkeley graduate student in environmental science and public policy. The researchers sampled 13 wells and 13 unimpacted wells that were in areas considered safe to drink water or that had already been cleaned of contamination. They also found arsenic in three wells that were dug in areas of high coal ash concentration and three wells that were dug nearby but that hadn't been in contact with coal ash. They also found arsenic in the groundwater in wells near inactive

coal-fired power plants and wells that were used to store treated coal ash. "Although some
